(57) An improved sample card is provided. The improved card, typically used in biochemical analysis, achieves high sample well capacity and improved fluid flow, including by means of a plurality of through-channels which route the fluid flow of samples along both the front and back surfaces of the card. Elevated bubble traps are provided, as are integral interrupt slots for sensing card position and alignment. A beveled leading edge facilitates insertion.

EP 0 745 856 A2

D scription

This invention relates to an improved sample card; more particularly, it relates to an improved sample card for analyzing biological or other samples.

Biocards have been used to analyze blood or other biological samples in a spectroscopic or other automated reading machine. Such machines receive a small biocard, roughly the size of a playing card, in which biological reagents, nutrients or other material is deposited and sealed, prior to injection of patient samples.

The biocard contains the reagents and receives the patient samples in a series of small wells, formed in the card in rows and columns and sealed, typically with tape on both sides. The biocards are filled with patient sample material through fine hydraulic channels formed in the card. The microorganisms in the samples may then be permitted to grow or reactions to proceed, generally over a period of up to a few hours, although the period varies with the type of bacteria or other substance analyzed and sample used.

After the incubation, the samples contained in the wells are placed in front of a laser, fluorescent light or other illumination source. The content of the sample in a given well can then be deduced according to readings on the spectrum, intensity or other characteristics of the transmitted or reflected radiation, since the culture of different bacteria or other agents leave distinctive signatures related to turbidity, density, byproducts, coloration, fluorescence and so forth. Biocards and machines for reading them of this general type for use in these biochemical applications can for example be seen in U.S. Patent Nos. 4,318,994; 4,118,280; 4,116,775; 4,038,151; 4,018,652; and 3,957,583.

Despite the general success of biocards in this area, there is an ongoing desire to improve the performance of the cards and readings on their samples. It is for example an advantage to impress more reaction wells in a given card, so that a greater variety of reactions and therefore discrimination of samples can be realized. A given facility may have only one such machine, or be pressed for continuous analysis of samples of many patients, as at a large hospital. Conducting as many identifying reactions on each sample as possible is frequently desirable, yielding greater overall throughput.

However, biocards that have been exploited commercially have often been limited to a total of 30 sample wells (or 45 wells in some designs). For compatibility with existing reading machines, the cards generally can not be enlarged from a certain standard profile (roughly 3 1/2" by 2 1/4"). Total well capacity has accordingly not grown beyond these levels, limiting the throughput on the machines.

It has also been the case that as the total number of reaction wells on a given card has increased, while the card size has remained constant, the wells have necessarily been formed increasingly close together.

With the sample wells crowding each other on the card, it has become more likely that the sample contained in one well can travel to the next well, to contaminate the second well. The threat of increased contamination comes into play especially as card well capacity increases above 30 wells.

It is accordingly an object of the invention to provide a biocard having an increased number of sample wells.

It is another object of the invention to provide a biocard with increased capacity, yet retaining overall standard card sizes.

It is another object of the invention to provide a biocard which can be loaded with samples quickly, easily and with a minimum of sample corruption.

It is another object of the invention to provide a biocard with improved disposal of injection bubbles arising during loading of the samples.

It is another object of the invention to provide a biocard which increase the effective fluid flow distance between adjacent wells, reducing well-to-well contamination.

It is another object of the invention to provide a biocard with better, smoother, more reliable fluid flow throughout the card.

The invention achieving these and other objects is an improved biocard having a significantly improved sample well capacity, easily achieving 45 wells, and reaching 64 wells and feasibly more. The biocard of the invention likewise provides carefully structured fluid channels which improve fluid flow, reduce bubbling yet improve disposal of any bubbles which do form through specially designed bubble traps.

The biocard of the invention provides, as well, improved security against well-to-well contamination, in part by increasing the effective distance that the samples in adjacent sample wells must travel to corrupt neighboring sites.

The invention will be described with reference to the drawings, in which like parts are labelled with like numbers. The drawings are briefly described below.

Figure 1 illustrates an improved biocard according to the invention, in a front planar view.

Figure 2 illustrates the improved biocard according to the invention, in a back planar view.

Figure 3 illustrates the improved biocard according to the invention, in a top edge view.

Figure 4 illustrates the improved biocard according to the invention, in a bottom edge view.

Figure 5 illustrates the improved biocard according to the invention, in a side edge view.

Figure 6 illustrates the improved biocard according to the invention, in an opposite side edge view.

Figure 7 illustrates a sample well with associated fill channel and bubble trap, according to the improved biocard to the invention.

A preferred embodiment of the invention is illustrated in Figures 1-7. This embodiment provides an improved biocard 100, having a generally rectangular

shape and in standard dimensions. Biocard 100 in the illustrated embodiment contains a total of 64 separate sample wells 110, each of which receives a sample, for example a biological sample extracted from blood, other fluids, tissue or other material of a patient, for spectroscopic or other automated analysis. The biological sample may be a direct sample from the patient, or be patient sample which is extracted, diluted, suspended, or otherwise treated, in solution or otherwise. Other types of samples, including antibiotic dosages or other material, can also be introduced for analysis. It will be understood that well capacities other than 64 can be used. Biocard 100 is generally used in a landscape orientation.

In terms of materials, biocard 100 may be made of polystyrene, PET, or any other suitable plastic or other material. Biocard 100 may be tempered during manufacture with a softening material, so that crystalline rigidity, and resultant tendency to crack or chip, is reduced. Biocard 100 for instance may be manufactured out of a blend of polystyrene, approximately 90% or more, along with an additive of butyl rubber to render the card slightly more flexible and resistant to damage. Biocard 100 may also be doped with coloring agents, for instance titanium oxide to produce a white color, when desired.

The biocard 100 of the invention may be of use in identifying and/or enumerating any number of microorganisms, such as bacterial and/or other biological agents. Many bacteria lend themselves to automated spectroscopic, fluorescent and similar analysis after incubation, as is known in the art. The transmission and absorption of light is affected by the turbidity, density and colorimetric properties of the sample. Fluorescent reactions may be performed as well, independently or along with spectroscopic or other measurements. If fluorescent data are gathered, use of a coloring agent in biocard 100 is preferable, since an opaque card reduces or eliminates the scattering of fluorescent emissions throughout the card, as can occur with a translucent material. Other types of detection and analysis can be done on biocard 100, including testing of susceptibility of microorganisms to antibiotics of different types, and at different concentrations, so that biocard 100 is a general-purpose instrument.

To receive sample fluid, the biocard 100 includes a sample intake plenum or port 120 at an upper right corner of the card 100, located on a perimeter edge of the card. The sample wells of card 100 contain dry biological reagents which are previously put in place in the wells, by evaporative, freeze-drying or other means, prior to being dissolved in solution with the injected patient sample for analysis. Each well can hold a deposit of a different reagent, for identifying different biological agents, if desired.

Intake port 120 receives a fluid injection tip and related assembly (schematically illustrated as 130), through which the sample fluid or other solution which arrives to dissolve the biological reagent is injected, un-

der a vacuum pulled on biocard 100 (typically .7-.9 PSIA), then released to atmospheric pressure. Injection port 120 includes a small intake reservoir 140 formed as a roughly rectangular hole through the card 100, which receives incoming fluid, and acts as a fluid buffer.

The fluid (patient sample or other solution) enters intake port 120, collects in intake reservoir 140 and travels along first distribution channel 150, located on the front or facing side of card 100. First distribution channel 150 consists of a relatively long channel formed in the surface of card 100, which extends substantially across the width of the card, and may have a cross section of approximately .1-.2 mm². First distribution channel 150 is tapped at intervals along its length by a series of parallel distribution legs or fill channels 160, which generally descend from channel 150 toward the sample wells 110 in each of the eight illustrated columns. When the sample is injected into the card, a short segment of the sample tip can be pinched off or heat sealed and left in place in intake port 120, acting as a sealing plug.

Fill channels 160 are relatively short channels (which may be kinked) which extend down from first distribution channel 140 into respective sample wells 110 located in the first row of card 100, and having a cross section of approximately .1-.2 mm².

It will be appreciated that each of fill channels 160 descend to and enter sample wells 110 at an angle, which results in the natural flow of the sample fluid down through the fill channels 160 by gravity, and resistance to small pieces of undissolved material flowing back up into the fluid circuitry. When the sample fluid actually enters the well 110, the fluid fills the well by action of both gravity and a vortex-type of flow effect into that well. Also, any of the fill channels 160, as schematically illustrated in Figure 7, as well as other connecting fluid channels in the invention may be preferably formed in full-radius style, that is, as a semicircular conduit, rather than a squared-off channel as in some older designs. The full-radius feature has been found by the inventors to reduce friction and fluid turbulence, further enhancing the performance of biocard 100.

Each of sample wells 110 in the first and other rows includes an associated bubble trap 170, connected to sample well 110 at an upper corner of the well, and located at a height slightly above the well on the card surface. As illustrated in Figure 7, each bubble trap 170 is connected to its respective well by a short trap connecting conduit 180, formed as a hollow passage part-way into the card surface and forming a short conducting path for trapped gaseous bubbles which have been formed in, or communicated to, the well 110 during the injection operation, by bacterial or other biological reaction, or otherwise. Bubble trap 170 does not cut through the card completely, instead consisting of a depression or well of roughly cylindrical shape, with a rounded bottom contour, and a volume of approximately 4.2 cubic mm in the illustrated embodiment.

Because the bubble trap 170 is located at an ele-

vated position above each respective well 110, any gaseous bubbles will tend to rise and be trapped in the depression of trap 170. With gaseous remnants led off to the bubble trap 170, analytical readings on the biological sample can be made more reliably, since scattering and other corruption of the microbial radiation reading by gas is reduced or eliminated.

As will also be understood from the following, the two-sided nature of biocard 100 permits fluid channels to be formed opposite to non-penetrating bubble traps 170, on the other side of the card. Some older card designs have employed bubble traps which penetrate through the card, eliminating the possibility of surface channels being routed in their vicinity.

In addition to the introduction of fluid through the path of first distribution channel 150, fluid also travels to wells below the first row of wells through other directions. More specifically, intake port 120 also connects to a second distribution channel 190 formed on the opposite or back surface of the biocard 100, second distribution channel 190 also leading away from the intake reservoir 140. Second distribution channel 190 also extends substantially along the width of card 100, but on the rear surface of the card. Second distribution channel 190 has a cross-sectional area of approximately .2-.3 mm².

Second distribution channel 190 is tapped above each of the eight illustrated columns of sample wells by a triplet of additional distribution legs or channels 200. Each of triplet legs 200 contains three relatively short connecting channels leading down from second distribution channel to a set of three respective through-channels 210 formed through the body of card 100.

Through-channels 210 are small apertures, approximately 1 mm in diameter, formed cleanly through the body of biocard 100, forming conduits or vias from one surface of the card to the other. The channels of triplet legs 200 connect to the respective through channels 210, which in turn are connected to additional well fill channels 220, forming a short link to three additional respective sample wells 110.

However, the fill channels 220 deliver the fluid to the sample wells from the opposite, that is rear, side of the card 100, creating a different fluid flow circuit which extends from intake port 120. That is, this path involves the second distribution channel on the rear surface of the card, through the body of the card by way of through-channels 210, then out to connecting fill channels 220 which deliver the sample to the well 110 (again at an inclined angle, providing gravity resistance to debris uptake).

The sample wells which receive the fluid from the second distribution through-channel circuit, like the sample wells which receive the fluid through the (front-planar) first distribution channel, also have bubble traps 170 associated with them, in the same general above-well configuration.

The biocard 100 therefore includes four rows by

eight columns of sample wells built up by connecting channels through the first and second distribution channels. This provides a set of 32 sample wells. In addition, another contiguous set of samples wells, making up the remaining 32 wells for the total of 64, is also deployed along the bottom of the card body using through-channels.

More specifically, a third distribution channel 230 is in fluid connection with intake port 120, but traces a generally vertical path downward from the port to a third distribution through-channel 240, located at a lower right section of the card 100. Third distribution channel 230 and its corresponding third distribution through-channel 240 have slightly larger cross sections than the first two distribution channels and their through-channels 210, to accommodate larger fluid flow to a greater total number of destination wells (32, versus 8 and 24 wells, respectively).

The fluid flows down through the third distribution channel 230, into third distribution through-channel 240, and then splits into two subchannels. The first subchannel 250 on third distribution channel 230, located on the rear of card 100, is a widthwise channel extending along the lower base of the card, having a cross-section of approximately .2-.3 mm². Rising up from first subchannel 250 are another set of triplet legs 260, which generally resemble first triplet 200 but which extend upward from first subchannel 230, rather than downward.

However, triplet legs 260 perform the same basic function, delivering the fluid to another set of through-channels 270, identical to through-channels 210. Through-channels 270 in turn lead through the card body, that is, to the front of the card, to connecting fill channels 280, which are generally short concave links (which may be kinked) to respective additional sample wells 110. Fill channels 280 likewise enter the sample wells 110 at an inclined angle, from above.

The last fluid flow path is second subchannel 290, leading off of third distribution through-channel 240 along the front of card 100, in a generally horizontal or widthwise manner. Second subchannel 290 is connected to the last (eighth), bottom row of eighth sample wells 110 by another set of vertical connecting conduits 300, single conduits connecting to single wells. Conduits 300 are generally dog-legged in structure, enter the well at a slightly inclined angle, and the associated wells each also include an associated bubble trap 170.

It may thus be seen that through the use of through-channels penetrating the card body 110, along with carefully distributed links through a plurality of distribution channels, in the invention valuable surface area is freed up on the card, by allowing the necessary connecting channels to be split up between the front and rear surfaces of the card.

The fluid flow paths thoroughly dispersed over card 100, including both front and rear surfaces, also result in a longer total linear travel of the flowing fluid than conventional cards. This leads to the significant advantage

that the possibility of inter-well contamination is reduced. The well-to-well distance in fact in the illustrated embodiment comes to approximately 35 mm, significantly more than the 12mm or so on many older card designs.

The inventors have also observed that the rate of inter-well contamination varies with the square of the linear distance, so the elongated fluid paths significantly enhance the integrity of readings on the card. Contamination itself is a function of sample mixing (density of solution falling out of wells) and liquid molecular diffusion, both of which are discouraged by the relatively fine channel cross-sections in many sections of the overall fluid circuit, as well as overall path length.

The contamination rate is also reduced by the fact that the volume of the channels along the fluid circuit varies slightly along the overall circuit travelled by a given sample. That is, the through-channels, the three main distribution channels and other segments of the paths have cross-sectional areas which, although all relatively fine, may differ slightly. The change in volume over the path tends to retard the progression of contamination, as do dog-legged or kinked sections of connecting conduits.

All these structural adaptations cooperate in reducing the rate of inter-well contamination in the biocard 100. The inventors have, as one indication of contamination management, measured the time required for test dye to infiltrate a neighboring well in conventional biocards and the card of the invention. Contamination in a conventional, low-capacity, non-through-body card has been observed in approximately 2-4 hours. In the biocard of the invention under similar conditions, in contrast, the contamination time has been observed at 16-18 hours.

Besides contamination kinematics, the upper-placed bubble traps 170 also more efficiently scrub the sample wells 110 of gas bubbles which form after the sample injection. Samples are typically injected as noted by evacuating the card, introducing fluid at the intake and then releasing the vacuum pull, so that the whole fluid circuitry returns to atmospheric pressure. Vacuum filling of the card may typically be done over a period of 3-60 seconds, slower rates helping to reduce the tendency of bubbles to form. Those bubbles can ruin sample readings, so reducing them results in a smoother, more efficient, higher-capacity yet more reliable biocard.

In addition, the improved fluid circuitry of biocard 100, including full-radius fill and other channels, generally narrower channels than older card designs, width-variation and other features result in a high capture percentage of sample intake actually reaching the sample wells 110, which the inventors have calculated at as high as 90-95%. This compares with a capture percent in the 80s for older card designs.

For mechanical interaction with the automated reading machine, biocard 100 may also be provided with

a series of sensor stop holes 310, located along the bottommost edge of the card. Sensor stop holes 310, illustrated as regularly spaced, rectangular through-holes, permit associated photodetectors to detect when a biocard 100 mounted in a reading machine has come into proper alignment for optical reading. The sensor stop holes 310 are arranged in vertical register with the vertical columns of wells 110, so that the optical detection of the stop hole 310 corresponds exactly to positioning of the sample wells 110 before optical reading devices. Older biocards have been aligned by sensor holes which are formed not integrally with the card itself, but in carriages or other supports which are attached to the card at some point in the reading process, as for instance disclosed in U.S. Patent No. 4,118,280. These structures have however been prone to time-consuming maintenance, particularly requiring the mechanical calibration and lining up of the carriage with the cards, and photodetectors. Integral sensor stop holes 310 eliminate that type of difficulty.

The biocard 100 of the invention is formed in the illustrated embodiment, as shown in Figure 7, with a mold parting line 320 which is formed most of the way down into a sample well 110, toward the bottom of the card as opposing mold dies meet during manufacture. Older card designs often had the mold parting line, which forms a tiny lip in a fluid cavity, at an upper point (above midway) of the card. The upper mold parting lines could tend to induce annular bubble rings to form during filling, as well as reduce the efficiency of drying of antibiotics or other material during manufacturing. The use of a downward offset mold parting line 320 avoids these difficulties, as well as improving the efficiency of chemical or antibiotic dehydration during incubation, and may act as a slight aperture during light and fluorescence reading operations. As illustrated in Figure 7, the walls of the sample well, and other features, are usually formed at a slight angle or incline (typically 1-4°), as an artifact of conventional molding processes in which separating the molded part from opposing molding pieces is made easier with slight surface inclinations. The shifting of the mold parting line 320 to the bottom area of biocard 100 likewise results in a smaller inclined (roughly speaking, trapezoidal) area in the bottom of the sample well which can tend to trap material, slightly.

Another advantage of biocard 100 of the invention is that patient sample and other markings are not introduced directly on the card itself, in pre-formed segments, as for example shown in aforementioned U.S. Patent No. 4,116,775 and others. Those on-card stipplings and markings can contribute to debris, mishandling and other problems. In the invention, instead, the card may be provided with bar-coding or other data markings by adhesive media, but markings or pre-formed information segments are not necessary (though some could be imprinted if desired) and debris, mishandling, loss of surface area and other problems can be avoided.

Biocard 100 furthermore includes, at the lower left corner of the card as illustrated in Figure 1, a tapered bezel edge 330. Tapered bezel edge 330 provides an inclined surface for easier insertion of biocard 100 into, carrouseles or cassettes, into slots or bins for card reading, and other loading points in the processing of the card. Tapered bezel edge 330 provides a gently inclined surface, which relieves the need for tight tolerances during loading operations.

Biocard 100 also includes a lower rail 360 and an upper rail 370, which are slight structural "bulges" at along the top and bottom areas of the card to reinforce the strength and enhance handling and loading of the biocard 100. The extra width of lower and upper rails 360 and 370 also exceeds the thickness of sealing material, such as adhesive tape, that is affixed to the front and back surfaces of biocard 100 for sealing during manufacture and impregnation with reagents. The raised rails therefore protect that tape, especially edges from peeling, during the making of the biocard 100, as well as during handling of the card, including during reading operations.

Upper rail 370 may have serrations 390 formed along its top edge, to provide greater friction when biocard 100 is transported in card reading machines or otherwise using belt drive mechanism. Lower card rail 360 may also have formed in it reduction cavities 380, which are small elongated depressions which reduce the material, weight and expense of the card by carving out space where extra material is not necessary in the reinforcing rail 360.

In terms of sealing of biocard 100 to contain reagents and other material, it has been noted that sealing tapes are typically used to seal flush against biocard 100 from either side, with rail protection. Biocard 100 also includes a leading lip 340 on lower card rail 360, and on upper card rail 370 which projects slightly over the leading edge of the card. Conversely, at the opposite end of the biocard 100 there is a trailing truncation 350 in both rails. This structure permits sealing tape to be applied in the card preparation process in a continuous manner, with card after card having tape applied, then the tape cut between successive cards without the tape from successive cards getting stuck together. The leading lip 340 and trailing truncation 350 provides a clearance to separate cards and their applied tape, which may be cut at the trailing truncation 350 and wrapped back around the card edge, for increased security against interference between abutting cards.

Claims

1. A sample card characterised in that it comprises:

a card body having first and second surfaces;
an intake port formed in the said card body;
a plurality of sample wells formed in the said

card body; and

at least one fluid flow distribution path, operatively connected to the said intake port, traversing at least a portion of the first and second surfaces and in fluid communication with the said sample wells.

2. A sample card as claimed in claim 1 wherein the first and second surfaces are planar parallel surfaces of the said card body and the said fluid flow distribution path passes through the said card body, preferably the said fluid flow distribution path comprising a plurality of fill channels in fluid communication with the said sample wells by one or more through-channels passing through the said card body, preferably the said fill channels having a full-radius configuration over at least a portion of the length thereof.
3. A sample card as claimed in claim 1 or claim 2 wherein it further comprises bubble traps in fluid communication with the said sample wells, the said traps being positioned at least partly above the said wells, preferably each sample wells having associated there with one bubble trap, connected to the sample well by a connecting channel.
4. A sample card as claimed in any of claims 1 to 3 wherein it further comprises integral interrupt slots for aligning the card for taking a reading, preferably the said interrupt slots being configured for triggering photoelectric detectors.
5. A sample card as claimed in any of claims 1 to 4 wherein it is formed by molding and the mold part is offset from the centre line of the sample card.
6. A sample card as claimed in any of claims 1 to 5 wherein it is sealed with an adhesive sealant on one or more surfaces of the card, preferably the sample card further comprising:

a leading lip on a front edge thereof; and
a trailing truncation ridge on a rear edge thereof, the said leading lip and the said trailing truncation ridge preventing the sticking together of adhesive sealant on abutting cards.

7. A sample card for containing a fluid sample subject to analysis by an optical system and having a plurality of sample wells in fluid communication with a fluid sample intake port, characterised in that it comprises:

at least one sensor stop hole in the said card positioned in registry with the said sample wells,
whereby optical detection of the said sensor

stop hole by the said optical system permits accurate alignment of the said wells with the said optical system as the said sample card moves relative to the said optical system for reading of the said wells, preferably the said sample card further comprising a peripheral edge portion, the said at least one stop hole being located in the said peripheral edge portion, preferably the said wells being arranged in a plurality of columns, a sensor stop hole being placed in registry with each of the said columns of wells, preferably the said sample card further comprising a peripheral edge portion, the said columns of wells being equidistantly spaced from each other in an array of sample wells and the said sensor stop holes being positioned in the said peripheral edge portion equidistantly spaced from one another.

8. A sample card for use by a reading machine having a sample card transport system characterised in that it comprises:

a card body defining a top surface and a bottom surface, a fluid intake port and at least one edge region, the said body defining a plurality of sample wells placed between the said first and second end regions and the said first and second side regions, the said edge region having a knurled texture surface increasing the friction between the said sample card and the said transport system; preferably the said edge region comprising first and second edge regions parallel to each other between the said first and second end regions and disposed on opposite sides of the said card body, the said knurled texture region being disposed on the said first edge region and the said second edge region having a slanted portion at the intersection of the said second edge region with one of the said first and second end regions.

9. A sample card characterised in that it comprises:

a card body defining a top surface and a bottom surface, a fluid intake port and a plurality of sample wells placed between first and second end regions and first and second side regions; and
a fluid channel network comprising a first distribution channel in communication with the said fluid intake port and a second distribution channel connecting the said first distribution channel with at least two of the said plurality of sample wells;
the said first and second distribution channels having different cross-sectional areas, thereby inhibiting potential cross-contamination between the said wells.

10. A sample card characterised in that it comprises:

a card body defining a first surface and a second surface, a fluid intake port and a plurality of sample wells placed between first and second end regions and first and second side regions; and
a fluid channel network comprising a first distribution channel in communication with the said fluid intake port and a second distribution channel connecting the said first distribution channel with at least two of the said plurality of sample wells, the said first and second fluid channels being provided in a first surface of the said card; the said fluid channel network further comprising a third distribution fluid channel in communication with the said fluid intake port, a fourth distribution channel connected to the said third fluid channel, and a through-card fluid channel connected to the said fourth fluid channel and linking the said fourth fluid channel with one of the said plurality of sample wells, the said third and fourth fluid channels being provided in a second surface of the said card; whereby the said first and second fluid channels in the said first surface of the said card and the said third and fourth fluid channels in the said second surface of the said card increase the separation distance between the said wells of the said card, thereby reducing the risk of contamination between the said wells; preferably each of the said sample wells comprising a bubble trap connected thereto by a connecting conduit with the said connecting conduit formed in the said first surface of the said card, but not in the said second surface, the said bubble traps comprising one or more depressions in the said first surface of the said card extending part-way through the said card, the said bubble traps thereby formed being in an elevated position with respect to the said sample wells.

11. A sample card characterised in that it comprises:

a card body defining a first surface and a second surface, a fluid intake port and a plurality of sample wells disposed between the said first and second surfaces; and
a fluid channel network connecting the said fluid intake port to the said wells;
each of the said sample wells comprising a bubble trap connected thereto by a connecting conduit with the said connecting conduit formed in the said first surface of the said card, but not in the said second surface, the said bubble traps comprising one or more depressions in the said first surface of the said card extending part-way

through the said card, the said bubble traps thereby formed being in an elevated position with respect to the said sample wells.

12. A sample card for containing a fluid sample subject to analysis by an optical system characterised in that it comprises:

a card body defining a first surface and a second surface, a fluid intake port and a plurality of sample wells placed between first and second end regions and first and second side regions;

a fluid channel network comprising a first distribution network in a first side of the said card and a second distribution network in a second side of the said card, the said first and second distribution networks conducting fluid samples from the said fluid intake port to the said sample wells;

each of the sample wells comprising a bubble trap connected thereto by a connecting conduit formed in the said first surface of the said card, but not in the said second surface, the said bubble traps comprising one or more depressions in the said first surface of the said card extending part-way through the said card, the said bubble traps thereby formed being in an elevated position with respect to the said sample wells; and

at least one sensor stop hole in the said card positioned in registry with the said sample wells, whereby optical detection of the said sensor stop hole by the said optical system permits accurate alignment of the said wells with the said optical system as the said sample card is moved relative to the said optical system for reading of the said wells;

preferably the said wells being arranged in a plurality of columns, a sensor stop hole being placed in registry with each of the said column of wells.

13. A test sample card characterised in that it comprises a rectangular card body having a first side portion, the said card body moved relative to an optical system in a direction parallel to the said first side portion, the said card body defining a plurality of sample wells arranged in an array on the said card body, the said wells having a well length defining a major axis and a well width defining a minor axis, with the said well length greater than the said well width, the said wells being arranged in the said card body such that the said major axis of the said wells is oriented substantially parallel to the said first side portion of the said card body, preferably the said wells being arranged in an array of columns of wells in the said card body, with each of the said wells in

the said columns of wells arranged in a manner such that the said major axis of the said wells is arranged in the said card body substantially parallel to the said first side portion of the said card body.

14. A sample card as claimed in claim 13 wherein the said card body further comprises a top surface, a bottom surface, a sample entry port and a fluid distribution channel network disposed in both the said top surface and the said bottom surface, the said fluid distribution channel network operatively connecting the said sample entry port to the said wells, and optionally a knurled texture area applied to the said first side portion of the said card body.

15. A test sample card characterised in that it comprises:

a substantially flat card body having a first surface and a second surface, first and second side regions and an end region between the said first and second side regions;

a plurality of sample wells;

a sealant tape applied in a strip to the said first and second surfaces to seal the said wells;

a pair of raised rails adjacent to the said first and second side regions disposed on and extending substantially the entire length of at least one of the said first and second surfaces;

the said raised rails terminating adjacent to the said end region and displaced inwards towards the said wells thereby to define a shelf portion in the said card body extending substantially across the said end region;

the said shelf portion providing a cutting surface for supporting a cutting blade for trimming the said sealant tape after the said sealant tape has been applied to the said at least one of the said first and second surfaces of the said card body; preferably the said raised rails being applied to the said first and second surfaces of the said card to form shelf portions in the said first and second surfaces of the said card.

16. A sample card as claimed in claim 15 wherein the said raised rails terminate adjacent to the said card body in a ramp, thereby facilitating the stacking of multiple test sample cards without scuffing of the said sealant tape applied to the said cards.

(54) **Test card for performing assays**

(57) An improved sample card (100) is provided. The improved card, typically used in biochemical analysis, achieves high sample well (110) capacity and improved fluid flow, including by means of a plurality of through-channels (150, 160) which route the fluid flow of

samples along both the front and back surfaces of the card (100). Elevated bubble traps (170) are provided, as are integral interrupt slots for sensing card position and alignment. A beveled leading edge (330) facilitates insertion.
